CUSTOMER SUCCESS GROUP ASSESSMENT

The Success Roadmap

How Okonkwo FinTech turns product usage data into a scalable Customer Success process for BukkiBooks

THE CASE IN BRIEF

Early Signal, Why it matters

1

SIGNAL

Reconciliation usage stopped for five weeks

›

2

DIAGNOSIS

New store manager was never trained on the feature

›

3

INTERVENTION

Training, a guide, a follow-up, a bulk-upload tool

›

4

OUTCOME

Emeka renewed and upgraded at year end

Important caveat: a separate Support fix and an unnamed decision-maker mean this isn't a clean cause-and-effect story.

THE ASSESSMENT QUESTION

Risk Stratification Checklist

?

Who gets the attention?

The case doesn't say how Okonkwo decides which accounts get proactive care or who is missed while one account is reviewed.

?

How does it work at scale?

Nothing explains how usage data applies across thousands of SME customers, not one dashboard read account by account.

?

What does it cost to serve?

The balance between high-touch attention and the cost of serving a large customer base is left entirely open.

Our answer: read usage as a signal, add customer context, prioritise human attention, and automate the repeatable steps.

Nigerian SMEs Are the Market Current Data

96%

of all businesses nationwide

84%

of total employment

But not a uniform market

Digital maturity varies widely: some SME owners still rely on manual processes; adoption depends on perceived usefulness, cost, security and trust, not one factor.

Financial institutions already segment customers by behaviour and value, and monitor declining usage to trigger proactive engagement.

A single one-size-fits-all approach will not serve them all.

Churn warning signs

EVIDENCE	LIMITATION	IMPLICATION
A study of 3,959 B2B software subscriptions found usage data added real predictive value to churn modelling.	Usage data shows what changed, not why. Feature-usage correlations can mislead if not validated.	Use data to detect a change. Use human judgement to assess it, before treating it as a health signal.

One more caution: usage trajectories differ between customers: no single inactivity threshold should apply to every BukkiBooks account without testing it first.

Invoicing, How it works

Only feature-level tracking caught it

Reconciliation falls to zero from Week 5 while every other feature holds steady. A total-session or total-login count would have averaged this out and missed it entirely.

This is the pattern the process on the next slides is built to catch: automatically, every week, for every account.

PROPOSED STRATEGY

How Automation Helps

Monitor › Detect › Assess › Segment › Prioritise › Route › Intervene › Measure

AUTOMATION

Detects change, triggers alerts, creates tasks, delivers routine education.

HUMAN CUSTOMER SUCCESS

Diagnoses why behaviour changed, understands goals, decides the response, owns the relationship.

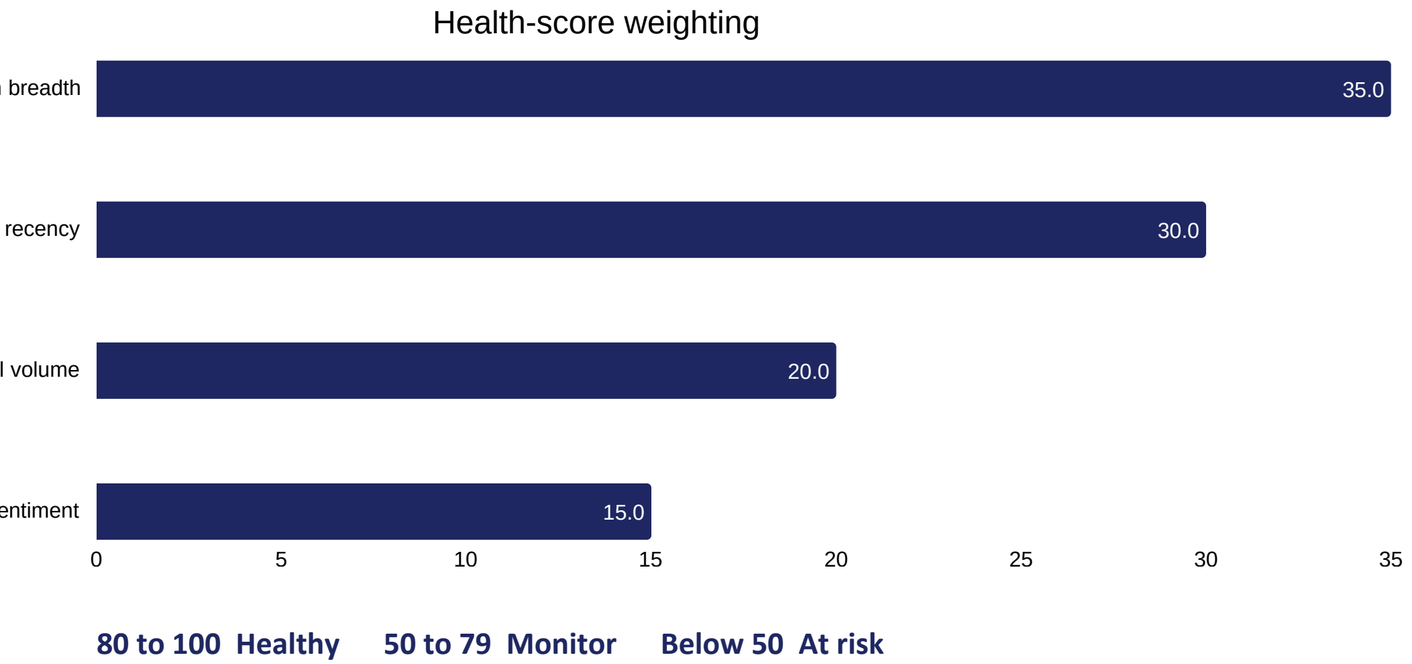

CUSTOMER SUPPORT

Resolves technical bugs, access issues and individual case tickets.

Automation identifies the signal. Customer Success understands the reason.

PROPOSED STRATEGY

Health Score Signaling

80 to 100 Healthy **50 to 79 Monitor** **Below 50 At risk**

Feature Abandonment Alert

Key feature unused for 14 consecutive days: auto-flagged and routed to the CSM.

Silent Freeze Alert

Weekly activity drops 30%+ against baseline: a check-in task is created automatically.

Applied to Ihuoma: Reconciliation drops −100% while Invoicing and Payments stay healthy, and this is what pulls the score into Monitor.

Priority Ranking

Segment	What the data shows	Treatment
Healthy · 80 to 100	Stable or rising usage	Automated education, no CSM time
Needs attention · 50 to 79	Early decline, feature drop-off	Automated nudge, CSM watches
At risk · below 50	Sharp drop, inactivity, tickets	CSM outreach, recovery plan
High value + at risk	Large SME account going quiet	Immediate CSM call, same day

PRIORITY RANKING

VERY HIGH Large decline + support issues + high value

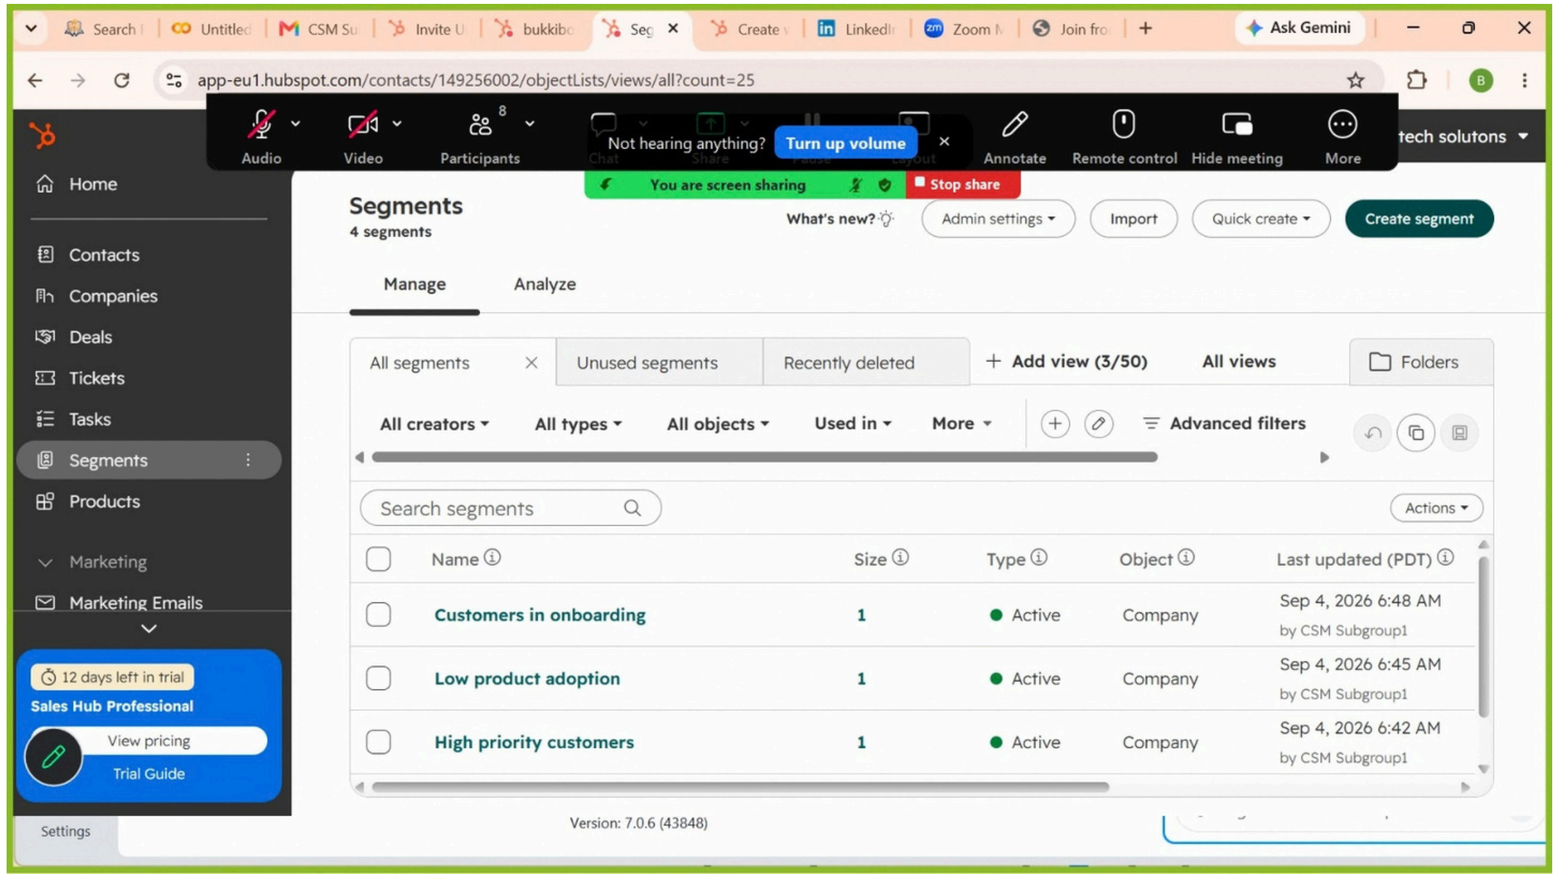

HIGH Large decline, renewal within two months

LOW Small decline, renewal ten months away

Rank = risk severity × customer value × renewal proximity × number of signals

Cost control: automated tiers absorb the long tail of SME accounts, so high-touch attention stays affordable at thousands of customers, the balance the case study leaves open.

Segments in Hubspot

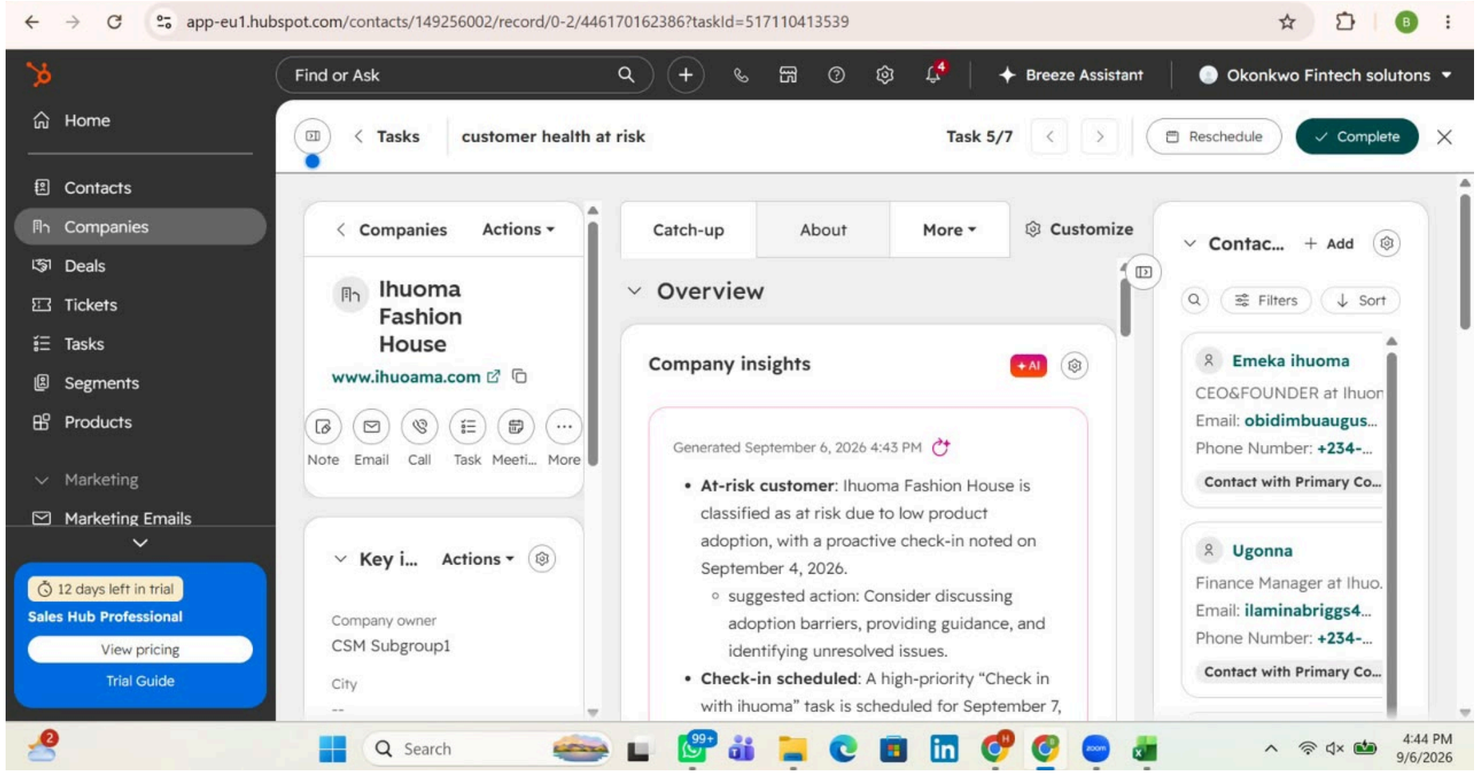

FROM AN EARLIER PASS AT THE BUILD

Customers in onboarding, Low product adoption, High priority customers: the same segmentation logic as the process on the last two slides, tried in a separate pass at the build.

Unedited screen recording still from an earlier build session, shown as captured, screen-share overlay included.

Hubspot record

The actual HubSpot record for Ihuoma Fashion House, in our build

WHAT THE SYSTEM WROTE, UNPROMPTED

"At-risk customer: Ihuoma Fashion House is classified as at risk due to low product adoption, with a proactive check-in noted."

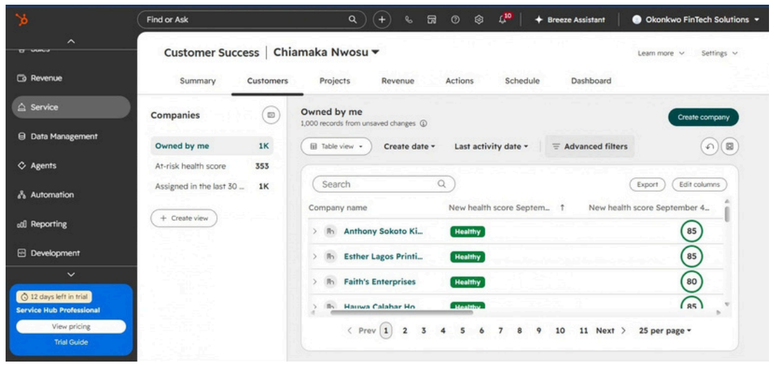

"Check-in scheduled: a high-priority 'Check in with Ihuoma' task is scheduled."

Same customer, same low-adoption signal, same recommended check-in as the case study, generated by the system, not written by us.

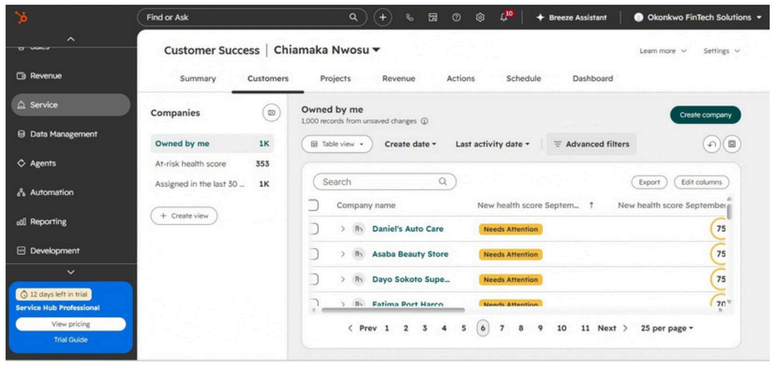

Demo built with simulated data in HubSpot. BukkiBooks is a fictional product; this account record and AI note are real.

Health score values

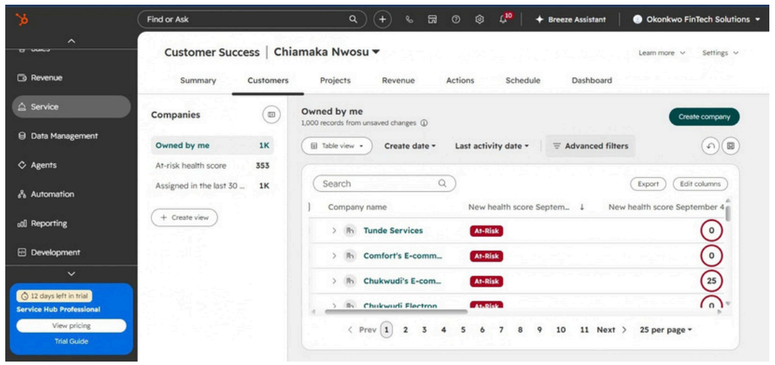

HEALTHY · 80 TO 100

NEEDS ATTENTION · 50 TO 79

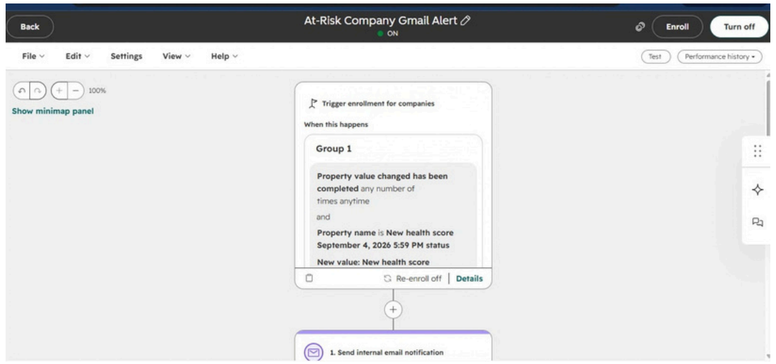

AT RISK · BELOW 50

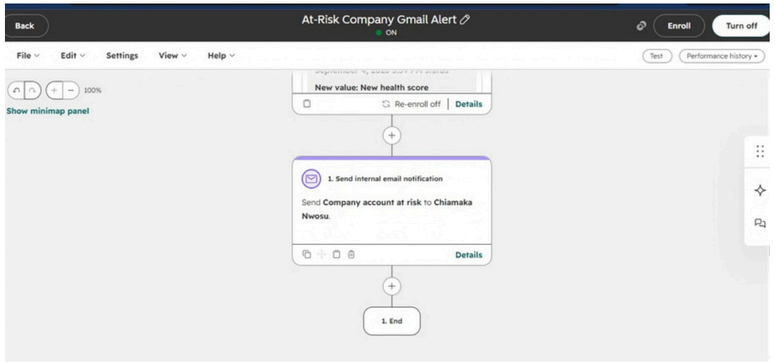

The At-Risk segment isn't a manual tag: it's a live HubSpot filter on the health-score property, currently isolating 353 of 1,000 accounts automatically, re-scored as the underlying usage data changes, not re-tagged by hand.

Demo built with simulated data in HubSpot. BukkiBooks is a fictional product; the accounts, scores and segments are real.

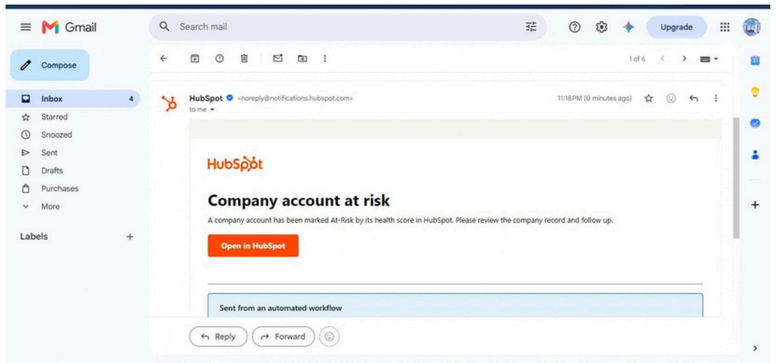

Automation set-up

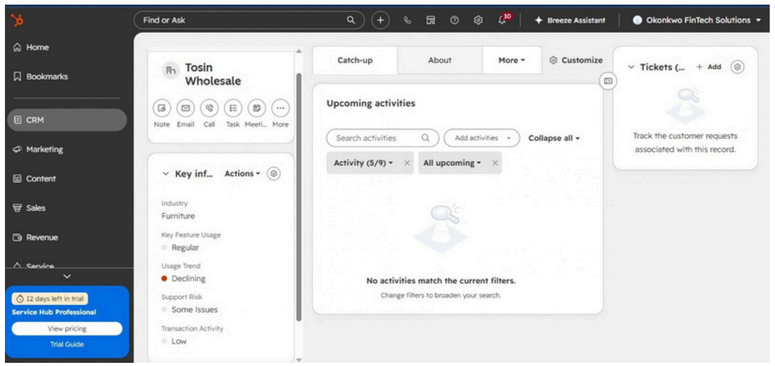

1. Health score crosses the threshold

2. Workflow sends an internal alert to Chiamaka

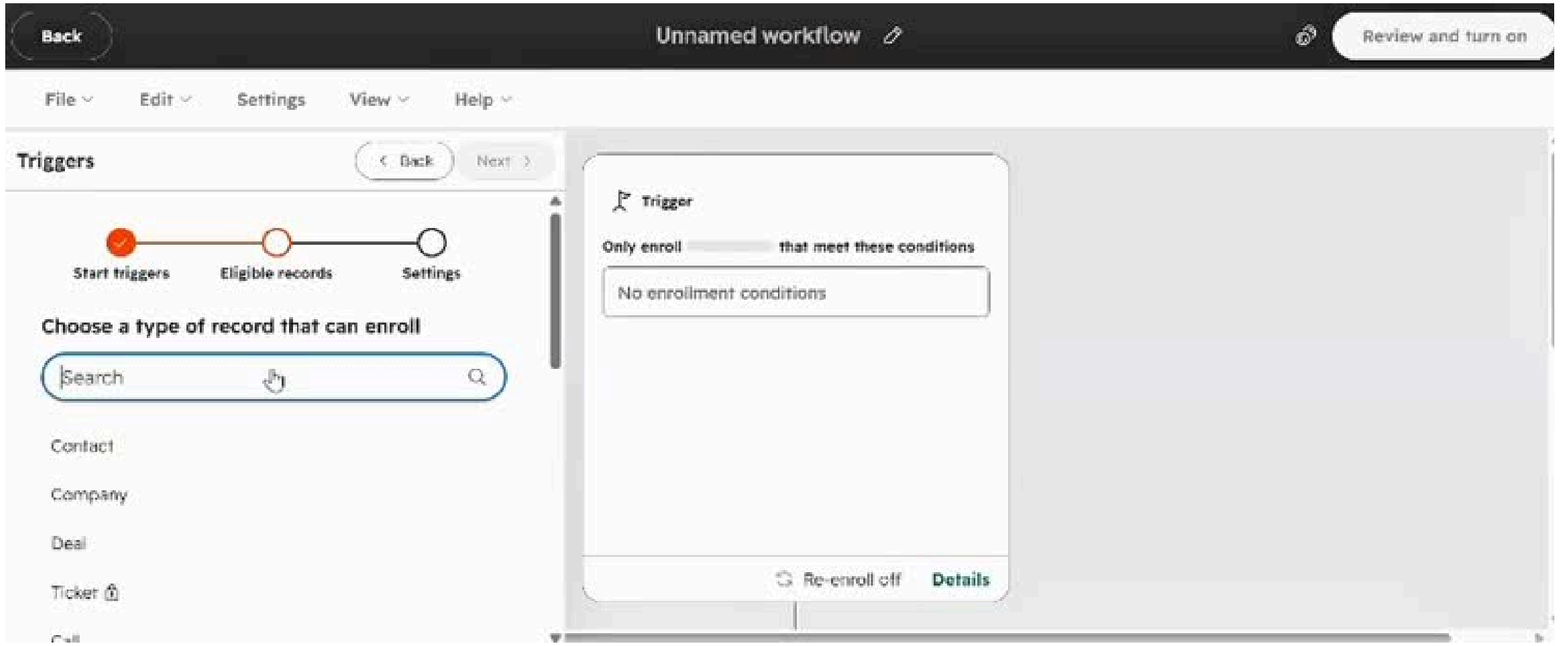

3. The alert lands in Gmail, real and timestamped

4. The CSM opens the record and sees why

Demo built with simulated data in HubSpot and Gmail. BukkiBooks is a fictional product; the workflow, alert and record are real.

Automation set-up, on video

WHAT THE RECORDING SHOWS

The HubSpot workflow being built live: enrolment conditions set against the health-score property, the trigger reviewed, and the workflow turned on. It is the same automation shown as four still screenshots on the previous slide, captured here running end to end in a single unedited take.

Customer Success ≠ Customer Support

CUSTOMER SUCCESS · PROACTIVE	CUSTOMER SUPPORT · REACTIVE
Monitors usage & health data to catch problems early	Responds to a specific issue the customer raises
Owns adoption, retention and account growth	Owns speed and accuracy for one bounded problem
Initiates check-ins, training and feature rollout	Fixes what’s broken, no account strategy needed
Measured on renewal, expansion & adoption	Measured on response time, resolution & CSAT

Core distinction: Support closes loops. Customer Success opens conversations.

Team synergy

Customer Issue › Support Owns Resolution › Support Activity Visible › CSM Monitors Health › Health Score Drops › HubSpot Alerts CSM › CSM Takes Action

APPLIED TO IHUOMA FASHION HOUSE

Ifeoma (Support) fixed a separate invoicing bug and owned that ticket to resolution. Chiamaka (Customer Success) owned the relationship and the training gap. Neither took over the other's work, but Chiamaka kept visibility into support activity, especially anything recurring or engagement-affecting.

Both teams work the same customer without competing for account ownership.

Risks and Mitigation Plans

RISK 1

Data shows the drop, not the reason

A usage dip flags a change; it can’t explain it. Ihuoma’s dashboard showed disuse, not that the manager was untrained.

Mitigation: treat the alert as a trigger for investigation, not a diagnosis. The CSM reviews, contacts the customer, and logs the real cause.

RISK 2

Alert fatigue from over-flagging

If every minor usage change triggers a notification, CSMs are flooded and can’t tell which accounts truly need attention.

Mitigation: segment and prioritise. At-risk gets immediate attention, Needs Attention gets scheduled outreach, Healthy stays automated.

TOOLS

Our Tool Stack

WHAT WE ACTUALLY USED

HubSpot
The CRM: accounts, health scores, segments, the workflow, the alert

Gmail
Where the automated at-risk alert actually lands

Claude AI
Generated the simulated customer accounts and usage data

Excel
Structured and prepped that data before import

Calendly & Zoom
Scheduling and hosting customer check-in calls

Zendesk
Escalation path for technical and support issues

WHAT A PRODUCTION BUILD WOULD ADD

Mixpanel
Dedicated product-usage event tracking, not connected here since BukkiBooks is fictional

Gainsight
Purpose-built CS health-scoring and segmentation platform

Zapier
Automation and routing at higher volume than a single workflow

Intercom
Targeted in-app education and self-service content

Everything on the left is real, tested end to end. Everything on the right is what we'd add to run this at production scale.

RECOMMENDATION

Automate Early

1. Automate detection across every account, every week
2. Contact the customer for a clear picture
3. Route technical issues to Support, not Customer Success
4. Measure customer outcomes, not alert or contact volume

This is the process that would have caught Ihuoma in week one, not week five.

Thank You
